"A New Microbiological Method For the Determination of Tryptophan," M. N. Meysel,
N.P. Trofimova, Inst Microbiol, Acad Sci USSR, Moscow

^KMicrobiol, Vol 22, No 4, pp 385-390

Developed a new strain, *Saccharomyces cerevisiae* T-1, which requires biotin, panthothenic acid, and tryptophan (or indole). Proposed selective elimination of tryptophan by destruction with ultraviolet light. Developed a new method for the quantitative determination of tryptophan by measuring the growth of a standard culture of yeast.

✓ New method for accelerated microbiological assay
of vitamins. M. N. Meysel and N. A. Kosolapoff.
Doklady Akad. Nauk SSSR, 91, 923-926 (1953). — The time
requirement for vitamin detn. can be cut to 4-6 hrs. by the
use of radioisotopes. Thus introduction of ³⁵Se into grow-
ing yeast culture permits a rapid detn. of rate of yeast
growth as affected by such substances as pantothenic acid
or pyridoxine. Typical calibration curves are shown.
G. M. Kosolapoff

Title : On the Biological Effect of Ionizing
Radiation

Orig Pub : V sb.; Deystviye oblucheniya na organizm.
M., Izd-vo AN-SSSR, 1955, 78-111

Abstract : The morphological, physiological, and biochemical changes in fermenting organisms caused by radiation with roentgen rays were studied. Parallel with the structural and biochemical changes, modifications of the functions of the microorganisms took place. It was found that in the cells of the microorganisms structures and biochemical systems exist which are either

Card 1/4

F-1

Abs Jour : Ref. Zhur-Biologiya, No 1, 1957, 496

Abstract : more sensitive or less sensitive to radiation. One of the more sensitive to radiation elements of the metabolism of the microbial cell is nucleic metabolism with the deoxyribonucleic system reacting to radiation with greater intensity than the ribonucleic system. Easily effected by radiation are also certain elements of carbohydrate metabolism with the result that an accumulation of sterines in the irradiated cells can be observed. The main elements of the cytochromic system are highly resistant to the action of irradiation. Thus, enzyme systems which are even connected with one or another of the cellular structures (chondriosoma)

Abs Jour : Ref. Zhur-Biologiya, No 1, 1952, 496

Abstract : are not equally damaged by irradiation. In the irradiated cells the connection between respiration (and fermentation) on one hand and difficult phosphorilization on the other hand is disturbed. A part of the energy of respiration and fermentation is expended wastefully and is not utilized by the irradiated cell. This expenditure increases with the increase of the doses of radiation. Considerably greater resistance to radiation appears in the process of the absorption of sulfates, methionine, and thiamine. Greatest sensitivity to radiation is displayed by the function of fission; somewhat more resistant is the function of

presented at the Atoms for Peace Conference, Geneva, Switzerland, 1955

APPENDIX I. M N

Specimens of Yersinia pestis were irradiated with gamma-radiation at the University of California Radiation Laboratory. A dose of approximately 10 million rads was given to each specimen. The specimens were then stored at -70°C until they were used.

The following table gives the results of the irradiation:

Specimen	Dose (Mrads)	Survival Rate (%)
1	10	100

3038. Early changes in bone marrow and blood of irradiated animals, as shown by fluorescence microscopy. M. N. Meissel and V. A. Sondak Dohl. Akad. Nauk. S.S.R., 1955, 105, 1221-1224; Referat. Zh. Biol. Khim., 1958, Abstr. No. 21345. Acridine Orange was injected into the blood of mice and rats before and after X-irradiation and after 2 hr the bone marrow was studied under the fluorescent microscope, the fluorescence being induced by blue light. In the controls the cell nuclei of the bone marrow took up the dye only feebly and fluoresced with a dull green light. In the irradiated animals (doses of 100-500 r) there were as a rule small cell clusters with intense bright green fluorescence. Such a fluorescence can be obtained by treating smears of bone marrow with the dye without preliminary injection into the blood. This is dependent on denaturative changes in the nucleoproteids, and is shown if the dye is mixed with Acid Fuchsin and Congo Red. By treating a smear of bone marrow with Acridine Orange with Acid Fuchsin (without Congo Red) a bright red fluorescence is obtained, depending on the changes in ribonucleic metabolism of the cells. Changes in fluorescence of the peripheral blood after irradiation are also described (Russian) T. R. PARSONS

McVay; M. A.

"Sterilization and Practical Problems Connected With Sterilization and Pasteurization by Radiation," by N. N. Karpov, Doctor of Biological Sciences, and N. D. Chernyayev, Candidate of Technical Sciences, Vestnik Akademii Nauk SSSR, No 11, Nov 56, pp 38-45

Radiation effects on microorganisms were studied for their theoretical value in providing information on the mechanism of the effects of radiation on simple organisms, such as microorganisms, and for the practical value of this problem since it is the basis for sterilization and pasteurization procedures.

The Institute of Microbiology, the Institute of Biophysics of the Academy of Sciences USSR, the All-Union Scientific Research Institute for Canning and Drying of Vegetables, and a number of other institutes are working on the problem of sterilization and pasteurization by radiation. Efforts are concentrated on: (1) explaining the mechanism of the injury and death of microorganisms and of other organisms under the effect of various types of radiation and by various methods; (2) studying the changes taking place in the products being sterilized and finding methods for eliminating these changes; (3) determining the harmlessness, nutritive value, and therapeutic effect of the products and of medical preparations sterilized by powerful radiation; (4) constructing rational apparatus for sterilization by radiation; and (5) developing methods for calculating doses of radiation required for sterilization.

Several R.G.P. values are quoted for specific items of food and drugs. Practical interest in sterilization by radiation lies in the use of synthetic radioactive cesium-137, and tantalum-182, which possess sufficient activity from gamma rays and have a long half-life. In addition, there is the field of solutions of radioactive isotopes.

The author concludes by saying that all these peaceful uses of radiation as applied to biology, medicine, and the food industry, require rational organization of work, centralized planning of projects and methods used in a definite field, coordination of the efforts of various institutions and their departments, and the equipping of the appropriate institutions with up-to-date sources of powerful radiations which are adapted to treating significant amounts of materials. (U)

To ensure complete sterilization from bacterial and spore contamination, and to decrease the ill effect that radiation has on milk, meat, vitamins, especially vitamin B₁₂, vegetables, etc., arising because of radiolysis of water, it is recommended that these products be sterilized in frozen condition, in a box containing some protective or stabilizing agents. Radiation can be successfully used to sterilize or stabilize instruments, and drugs such as antibiotics, protein preparations, anticoagulants, hormones, etc. It may also be used in surgical operations, which heal quite rapidly after their sterilization by radiation.

As for pasteurization by radiation, in most cases it is necessary only to check bacterial multiplication or to retard it, therefore the roentgen equivalent physical (r.e.p.) is in the range of thousands instead of millions as the case is for sterilization of products.

Influence of ultrasonic waves on steriod content of yeast
M. N. Meysel, R. D. Gal'tseva, I. F. Kipner and P.
Vakinaa Zhur. Onshchek Biol. 17, No. 4, p. 7 26, 1961
In yeast cells subjected to ultrasonic radiation the ergosterol
increases by 85-60%. This occurs in acid or alk. medium.
Ultraviolet, x-rays, or increase in temp. have no such effect.
In contrast to x-rays, ultrasonic waves have no effect on the
ergosterol content of yeast cells which, after irradiation,
were permitted to grow. The effect of ultrasonic waves
on ergosterol which is isolated from yeast is due to mech.
or physicochem. changes within the cells induced by the
ultrasonic vibration.

AUTHOR: Meysel, M. N., Doctor of Biological Sciences 30-58-3-17/45

TITLE: Congress on the Biology of Cells
(Kongress po biologii kletki)

PERIODICAL: Vestnik Akademii Nauk SSSR, 1958, Nr 3, pp. 80-83
(USSR)

ABSTRACT: The 9th International Congress took place in Sent-Endryus (Scotland). 380 scientists from 30 countries among which were also the USSR, Poland, Hungary and Czechoslovakia, attended this congress. The Soviet delegates were treated very attentively and all their reports were admitted, even those which were not announced previously. The municipal cinema was especially rented for the performance of the Soviet color-picture: "Biological Action of Radiations on Micro-Organisms". 172 reports were delivered altogether during the period of the congress (from August 28th to September 3rd 1957) which - with a few exceptions - were characterized by a high theoretical and methodical level. The Soviet delegates delivered the following reports:

Card 1/3

Congress on the Biology of Cells

30-58-3-17/45

- 1) V. G. Konarev: "On the Participation of Nucleic Acids in the Ontogenesis of a Plant Cell."
- 2) P. A. Utkin: "On the Interphase and Mitosis of Tissus Cells."
- 3) B. L. Astaurov: "On Diploid and Polyploid Parthenogenesis caused by high Temperature in 2 Species of Silkworms and their Hybrids."
- 4) M. N. Meysel': "On the Effect of Radiations on a Cell."
- 5) A. N. Studitskiy: "On the Rules Governing Muscular Regeneration."

A super (color) projected a film with pictures from mitosis. The author further states that the foreign works in the field of cytology cytophysiology and cytochemistry were very extensive and distinguished by a high methodical and technical level. Electron-microscopy and ultra-thin sections are largely applied, in which case the enlargement is steadily increased. Both the interference-microscopy and the micro-auto-radiography are introduced to a great extent. Highly sensitive counters for measuring the radioactivity, as well as a spectro-photometric, densitometric- and absorption-devices are used. Concluding, the

Card 2/3

Congress on the Biology of Cells

30-58-3-17/45

author states that modern cytology represents one of the leading fields of biology that it develops rapidly and shows great scientific and practical possibilities. Greater attention should also be paid to this problem in the Soviet Union.

TITLE:

The Effect of Ionizing Radiation Upon Amination, Desamination and Transamination Processes (Deystviye ioniziruyushchikh izlucheniy na protsessy aminirovaniya, dezaminirovaniya i pereaminirovaniya)

PERIODICAL:

Doklady AN SSSR, 1958, Vol. 118, Nr 1, pp. 75-77 (USSR)

ABSTRACT:

The authors made a special investigation of the processes of the amination of ketonic acids as well as of the desamination and transamination of amino-acids with the yeast cells, of the *Saccharomyces cerevisiae* after their irradiation with x-ray dosages of from 30 to 100 kiloroentgen. The yeast was investigated either immediately after irradiation or after from 24 to 48 hours growth. The amination of a ketonic acids was investigated by means of the method of M. Neber (ref. 6). The transamination of amino acids was investigated by means of the method of Braunshteyn and Kritsman (ref. 7). The experiments of the authors showed the following: immediately after the irradiation of yeast with a dosage of 60 kiloroentgen the transamination of amino-acids is only little disturbed. Only after 16-hours growth

Card 1/3

20-1-21/58

The Effect of Ionizing Radiation Upon Amination,
Desamination and Transamination Processes

it decreases by 20% and after 48 hours by 70-80%. With strong dosages of irradiation (100 kiloroentgen and more) the intensity of the transamination processes of amino-acids also reduces immediately after irradiation by about 50%. The desamination of amino-acids in the test samples as well as in the irradiated yeast samples were determined by means of the method of Neber (ref. 6). The desamination with irradiated cells immediately after irradiation differs only little or not at all from the reactions of the test samples. But with a further growth of the irradiated cells the desamination increases already after 16 hours (compared with the desamination in not-irradiated samples) 2-3fold and after 48 hours even more. Of the processes investigated here the amination of ketonic acids is most sensitive against irradiation. The changes in the carbon exchange of the irradiated yeast cells and its partial shift to the synthesis of fats and lipoides correlates well as regards time and quantity with the suppression of the amination process and less well with the suppression of transamination. The irradiation, in some respect, leads to the same consequences as does a lack of nitrogen in organism.

Preface: This book is intended for physicians, scientists, and engineers
as well as for students and students at universities where radiobiology and
radiation genetics are taught.

CONTENTS: This is Volume 3 of a 6-volume set of reports delivered by Soviet
participants at the Second International Conference on the Peaceful Uses of
Atomic Energy, held on September 1-13, 1958, in Geneva. Vol. 3 contains
32 reports edited by candidates of medical sciences S.V. Lebedintsev and V.Y.
Sobol'. The reports cover problems of the biological effects of ionizing
radiation, future consequences of radiation sickness, uses of radioactive isotopes
in radiation, treatment of radiation sickness, uses of atomic energy for diagnostic
and therapeutic purposes, soil absorption of uranium fission products,
and their absorption in plants and products.
References accompany each report.

TITLE:

Luminescence-serological Detection of Colonies of Bacteria
of the Intestinal Group (Lyuminestsentno-serologicheskoye
raspoznavaniye koloniy bakteriy kishechnoy gruppy)

PERIODICAL:

Doklady Akademii nauk SSSR '959, Vol '25 Nr ' pp 205-207
(USSR)

ABSTRACT:

The possibility of detecting very young (5-6 hours old) colonies
of Escherichia coli by means of luminescence was shown in
reference 4. For this purpose the back wall of the membrane
filter was treated with a fluorescent color (fluorescein) and
acridine-orange. The colonies of bacteria remain alive. Under
a luminescence lens or a microscope they can be taken away with
a capillary pipet for the purpose of a re-sowing. Under certain
conditions it is possible to differentiate the young bacteria
of the intestinal group. In 8-9 hours old colonies the authors
(together with Ye. N. Levina) found differences between the
colonies of the dysentery bacteria and the E. coli which
however cannot be regarded as completely reliable. The method
mentioned opened the way towards the finding of early stages
of phagolysis of the colonies (Ref 3). Luminescent sera have

Card 1/2

SOV/20 12^o - 54^o

Luminescence serological Detection of Colonies of
Bacteria of the Intestinal Group

In recent times has been successfully used for the discovery of the antigen or the antibodies in virology, microbiology, immunology and cytology. In the present paper the authors attempted to use the luminescent sera for the serological identification of young colonies of bacteria. For this purpose globuline fractions of the dysentery and Coli OB-serum were produced (by means of immunization of rabbits with a toxigenic strain of the bacteria *E. coli*). From the results the authors draw the following conclusions: 1) A direct fluorescence of young colonies of bacteria on membrane filters facilitated a rapid detection and quantitative determination of these colonies; it was, however, admitted that this way of identification is only in individual cases successful and achieved only with difficulty. 2) The luminescence-serological method as suggested by the authors means a further step towards the improvement of identification of such colonies. 3) An important characteristic of this method is the fact that the bacteria remain alive and can be further used. 4) The dysentery bacterium by Fleischer and the "toxic" strains of *E. coli* facilitated a rapid and reliable

Card 2/3

Luminescence-serological Detection of Colonies of Bacteria of the Intestinal Group SOV/20.125.-56/67

identification of very young colonies. It is quite obvious that the mentioned method will find a wide field of application. There are 6 references, 3 of which are Soviet

Report No. 30 Luminoscopy, 8th, 1957

Study Luminoscopy methods, materials, methodology (Methods for Luminescence analysis, Materials of the 8th Conference) Moscow, 1957.

All USSR, 1960. 167 p. 1,000 copies printed.

Sponsoring Agency: Academy of Belorussian SSR. Institute of Physics.

Editor: M. A. Borovitsch, Ed.; L. Tsvetkov; Tech. Ed.

E. Stavro.

PURPOSE: This collection of articles is intended for chemists and phys. scientists interested in molecular luminescence and for scientific personnel concerned with applications of this and related phenomena in research in the life sciences.

CONTENTS: The collection contains 26 papers read at the Eighth Conference on Luminoscopy, which took place 10-12 October, 1959 [place of conference not given]. These studies are concerned principally with the development of new luminescence methods for quantitative and qualitative chemical analysis, and with the applications of luminescence in medical and biological research, and with the applications of luminescence methods for the determination of uranium, mercury, manganese, aluminum, boron, and other elements, as well as luminescence methods for the diagnosis of skin cancer and the detection of grippe virus, tuberculous microorganisms, etc. The structural design of one instrument is described. The conference was not concerned with studies on the phosphorescence of crystal phosphors. There is a discussion of the contributions of Soviet specialists to molecular luminescence in the course of the year and held preceding the conference. The articles of V. I. Neimanov (p. 75) and of V. V. Parkhase (p. 79) have been annotated because of their importance. No publications are mentioned. References to some of the articles:

TITLE:

Ultraviolet luminescence of cells in mitotic division

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 141, no. 3, 1961,
723 - 725

TEXT: Cells and tissues grown outside the organism were studied: (a) human: an inoculated decent of amnion cells; (b) cultures of embryonic epithelium; (c) of fibroblasts; (d) animal: primary cultures of the kidneys of guinea pigs and monkeys. Single tissue cultures were grown on quartz glass and examined by ultraviolet-luminescence microscopy either living (in physiological salt solution) or after fixing by methanol. The methods had been described previously (Ye. M. Brumberg et al., Biofizika, 6, No. 1, 114 (1961); Ye. M. Brumberg et al. Taitolo-giya, 2, 589 (1960); Ye. M. Brumberg, Zhurn. obshch. biol. 27, No. 6,

Card 1/4

Ultraviolet luminescence of cells in... S/020/61/141/003/016/021
B103/B110

401 (1956)). Microphotographs showed that the cells undergoing mitosis differed from cells at rest in the following facts: The cells at rest weakly fluoresce; fluorescence increases already during the early prophase and reaches maximum intensity in the middle of the metaphase. Then, it slowly decreases; however, until complete separation of the daughter cells, it exceeds the fluorescence of the cells at rest undergoing interkinesis. The cell nucleus, unlike the total cytoplasm, does not fluoresce. Dark, not fluorescing chromosomes can be seen on the background of the cytoplasm. The absorption of shortwave ultraviolet rays ($250-270 \text{ m}\mu$) by the cells increases with rising intensity of fluorescence. Absorption and fluorescence patterns interrelated like a negative and a positive; in both images, however, the chromosomes remain dark. The fluorescence of cells at rest is not so constant as that of dividing cells. There are always individual groups of brightly fluorescing cells at rest. In most cases these are degenerating, perishing cells whose increasing fluorescence is not accompanied by increased ultraviolet absorption. Chromoscopic examination (Ye. M. Brumberg. DAN, 25, 473 (1939)) showed degenerating cells at rest and dividing cells are

Card 2/4

Ultraviolet luminescence of cells in ...

S/020/61/141/003/016/021
B103/B110

differently colored. Selective extraction of nucleotides, nucleic acids, and lipoids with perchloric acid in the cold and at 90°C, and with ribonuclease showed that the ultraviolet fluorescence of dividing cells is not due to the action of these extracted substances, except the bone marrow, the fluorescence of which rapidly decreases after extraction of nucleotides. The character of fluorescence cannot be changed by strong oxidizers and reducing agents (rongalite, potassium permanganate). 2% of urea somewhat increases the fluorescence of cells at rest. It is concluded that the intensity of fluorescence of cells undergoing mitosis is increased by high-molecular substances (most probably proteins containing cyclic amino acids) which are difficult to extract from the cell. This increase is possibly related to a reversible denaturation of protein in various physiological processes (muscular work). This might not be an absolutely formal analogy, since the occurrence of contractile proteins in the cell during mitosis had previously been proved. These proteins effect the mechanical work of chromosome separation and cell division. The muscles differ from other tissues in their particularly strong ultraviolet fluorescence. It is less probable that cell fluorescence during division should be increased by low-molecular substances

which are produced in metabolic shifts or accumulated. This means that these shifts occur only in certain stages of mitosis (Refs. 8 and 9, see below), whereas an increase of fluorescence could be observed during all stages of division. Experiments will be continued. Ye. S. Zalmanzon is thanked for supplying the tissue cultures. There are 11 references: 7 Soviet and 4 non-Soviet. TITLE: Importance of intracellular fat reserves for cell reactivation
after radiation injuries

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 142, no. 3, 1962, 699-701

TEXT: Cell reactivation after ultraviolet and ionizing irradiations is dependent on 1) character of radiation injuries, 2) state of cell activity, and 3) cell structure and function. This paper is a detailed study of the third factor, particularly of the regulating effect of intracellular fat reserves. The variation of nutrient media by additions of saccharose and glycocoll to obtain yeast cells rich in fats and lipoids and the subsequent effect on oxidation processes and radioresistance in irradiated cells have been described previously (Biofizika, 2, no. 1, 101 (1958)). In the present tests, the total content of fats and lipoids determined in 48 hr cultures of Endomyces magnusii (EM) by extraction with sulfuric ether was 11.5% (dry weight) on a suitable nutrient medium as compared Card 1/3 ✓

Importance of intracellular fat...

to 2.2% on unsuitable media. Cells were correspondingly termed as rich and poor in fat. 2% suspensions of both types were irradiated in a PyPi-M (RUP1-M) x-ray apparatus (210 kw, 15 ma, 3760 r/min, without filter). EM were irradiated with 150 and 250 kr and *Saccharomyces vini* with 100 kr. Cells and controls were subcultured in Petri dishes with agarized beer wort immediately after irradiation and kept 6 - 7 days at 28°C as 0.2 - 0.02% suspensions in sterile tap water with daily subculturing in wort agar dishes. Reactivation was judged from the percentage of colonies (colonies in nonirradiated controls = 100%). It has been found that EM cells rich in fat have much higher reactivation levels and radioresistances (Fig. 1). The state of the fat inclusions was studied in luminescent light in cells treated with aqueous solution of Nile blue. The intracellular fat proved to be utilized in the process of cell reactivation. The present studies confirm increased reactivation in cells rich in fats and prove that their reactivation level is much higher, particularly in the first 24 hr. There are 2 figures and 8 references: 6 Soviet and 2 non-Soviet. The reference to the English-language publication reads as follows: W. A. Pratt, W. S. Moos, M. Eden, J. Nat. Cancer Inst., 15, 4, 1039 (1955).

TITLE: Micronecrotic foci in the spleen of irradiated animals

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya biologicheskaya, no. 2, 1963, 232 - 239

TEXT: Luminescence microscopic studies were made of cell injuries in the spleen of albino rats. The animals were exposed to overall X-ray irradiation in doses of 100 - 1,000 r and killed at various intervals up to 24 h after irradiation. The preparations were fluorochromated intravitam or supravitam with acridine orange or with mixtures thereof and basic fuchsin or basic fuchsine and Congo red. Radiation-induced increase in the number of lymphocytes and changes of their nucleoprotein structure were observed already after 39 min of irradiation with 500 r. Groups of young lymphoid cells similar to micronecrotic foci detected previously in the bone-marrow of irradiated animals appeared at the same time. The number of these cell groups increased with rising dose, reached a maximum after 12 h approximately, whereupon it dropped sharply until the 14th

Card 1/2

Micronecrotic foci in the spleen of

S/216/63/000/002/004/004
A066/A126

hour after irradiation with 500 r. The lymphoid cells disappeared entirely after 24 h. Secondary and intrinsic luminescence were recorded using a special microscope. The pictures showed that ultraviolet absorption and ultraviolet luminescence increased markedly in the injured cells, especially in the micronecrotic foci. This applies not only to the cells but also to the detritus and to clusters of nucleoproteids and nucleic acids separating from the cells. As similar phenomena have been observed in the bone-marrow and in lymphatic nodes of irradiated animals, the increase in ultraviolet luminescence appears to be of general significance. The substances responsible for this effect are being studied. There are 4 figures.

AUTHOR: Seliverstova, L. A.; Maysel', M. N.

TITLE: Relationship between regeneration of irradiated cells and type of energy metabolism

SOURCE: AN SSSR. Doklady, v. 150, no. 6, 1963, 1366-1369

TOPIC TAGS: yeast cell, regeneration, irradiated cell, energy metabolism, aerobic oxidation, alcoholic fermentation

ABSTRACT: Yeast cell regeneration after ionizing irradiation was studied under conditions of aerobic oxidation and alcoholic fermentation. Each of the 2 species tested (1 strain each of *Saccharomyces vini* (*ellipsoideus*) and *Saccharomyces cerevisiae*) was grown in both agar-malt wort in Petri dishes (aerobic cultures) and in a thick layer of liquid wort in test-tubes (anaerobic cultures). After 48 hours' growth, the yeast was separated from the nutrient medium, rinsed with sterile tap-water, and subjected, as a 2% aqueous suspension, to x-irradiation (3560 r/min). Korogodin's method (Biofizika, v. 3, 1958, 2061) was used to assess

'Card 1162

L 12841-63
ACCESSION NR: AP300323I

O

regeneration. Dilute suspensions of irradiated and control yeast (final concentration of yeast cells 0.02%) were poured into sterile test-tubes and kept in the thermostat at 28°C. Every day, aerobic and anaerobic yeast cells were inoculated into agar-wort nutrient medium in Petri dishes and the number of colonies growing out was counted after 3 days. Statistical analysis of the results with *S. vini* showed 3.6 and 4.3% aerobic and anaerobic cells, respectively, to be capable of colony formation when inoculated immediately after irradiation; inoculated after 24 hours in water, 46 and 17% respectively, formed colonies; after 2 days, 50 and 22% and after 3 days, 79 and 41%. Results were similar with *S. Cerevisiae*, except that 4.1% anaerobic cells inoculated immediately after irradiation survived, as compared to 1.5% aerobic cells; after 3 days in water, however, 79% of the aerobic type were capable of regeneration, as against only 35% of the anaerobic type. Further experiments with *S. cerevisiae* grown for longer periods (2 weeks) under widely different aeration conditions and then irradiated confirmed the greater immediate sensitivity and greater ultimate regeneration of aerobically grown yeast cells. The observed differences in the regeneration of the two types of cell is attributed to the functional and structural reorganization of the cells occurring in the shift from aerobic to anaerobic conditions, and especially reorganization of the mitochondrial apparatus and respiratory enzyme system.

TITLE: A comparative investigation of the microscopic and
ultramicroscopic structure of irradiated *Saccharomyces vini* and
Rhodotorula glutinis yeast cells

SOURCE: *Mikrobiologiya*, v. 33, no. 2, 1964, 270-277

TOPIC TAGS: *Saccharomyces vini* yeast, *Rhodotorula glutinis* yeast,
X-irradiated yeast cell, structural comparison, yeast microscopic
structure, yeast ultramicroscopic structure, yeast radiosensitivity,
yeast mitochondrion damage, yeast metabolic process

ABSTRACT: *Saccharomyces vini* and *Rhodotorula glutinis* yeast cultures
which differ in radiosensitivity, structure, and metabolism were
investigated to compare the structural nature of radiation injuries.
Saccharomyces vini and *Rhodotorula* yeast cultures (24 hrs old) were
X-irradiated (RUP-1, 15 ma, 210 kv, no filter, focal length 9 cm,
3570 r/min) with single 100 kr doses. The irradiated yeast cells
were investigated by optic light microscopy and electronic microscopy

Card 1/3

ACCESSION NR: AP4031823

immediately after irradiation and again after 18 to 24 hrs growth. Survival of irradiated yeast cells was based on number of colonies grown on agar compared to number of nonirradiated yeast cell colonies. Findings show that the structural organization differences of Sacch. vini and Rh. glutinis yeast cells correlate with the metabolic specificity and radiosensitivity of these organisms. Obligate aerobic Rh. glutinis yeast is more radiosensitive than the well fermenting Sacch. vini yeast. Irradiation of yeast cells with doses that do not cause immediate death does not produce any sharp structural-morphological damage in the cells. Only during the metabolic process do molecular injuries of the functional structure develop into more serious injuries which are first revealed by electronic microscopy and then by optic light microscopy. After irradiation and during the following growth period the most distinct changes are found in the mitochondria. However, the injuries do not spread throughout the entire mitochondrial system and the remaining undamaged mitochondria apparently represent the cambium from which a new population of energy yielding cell structures develops. The lipoprotein cell membranes (mitochondrial and nuclear membranes, endoplasmic reticulum) are relatively radioresistant. Orig. art.

TITLE: Role of the mitochondria of lymphocytes in their response to ionizing radiation
22

SOURCE: AN SSSR. Izvestiya. Seriya biologicheskaya, no. 6, 1965, 884-897

TOPIC TAGS: ionizing radiation, radiation biologic effect, cell physiology, electron microscopy, rat, protein, biologic metabolism

ABSTRACT: Electron microscopic studies on the lymph nodes of white male rats exposed to large doses of ionizing radiation or at comparatively high dose rates revealed injury to the ultrastructure of lymphocytes within 4 to 5 minutes. The lipoprotein membranes of the cells organelles (cristae and mitochondrial membranes, nuclear membranes) were particularly affected, chiefly in the form of stratification and vacuolation of the two-layer membranes and destruction of the cristae. The changes appeared sooner in the mitochondria than in the nuclei and preceded structural injury to the nuclear nucleoproteins.

The fusion of injured mitochondria and intimate contact with the nuclear membranes were clearly demonstrated. A comparison of the results of this investigation with published data on early structural and ultra-

structural lesions and functional disturbances in mitochondria and nuclei of irradiated radiosensitive cells indicates that they are interdependent. The ready vulnerability of the comparatively few mitochondria and the ensuing impairment of the energy metabolism of the cells play an important role in the radiosensitivity of lymphocytes and cells with similar responses to radiation. The vulnerability of deoxyribonucleoproteins following irradiation of radiosensitive cells together with the impairment of their energy balance caused by injury to the mitochondria seem to be the factors responsible for the death of these cells in the interphase. Orig. art. has: 16 figures. [JPR]
